

(a) Stratified split

random, repeated over five seeds; capture time plays no part, so the three windows interleave

(b) Global chronological split

degenerate on GeNIS: the last 20% holds classes the first 60% never contains. Reported as a property of the corpus, not used as a protocol

(c) Per-class temporal split — the protocol evaluated here

the same 60/20/20 cut applied inside each class, so all nine remain present in all three windows

(d) What the two follow-up experiments move

both stay inside (c), and neither opens a partition it should not
